A network comprising:

a network fabric further comprising at least two switches and a plurality of links, each link connected to at least one switch of the at least one switch;

a first N_Port connected to a link of the network fabric;

a second N_Port connected to a link of the network fabric;

wherein there exists a first path and a second path from the first N_Port to the second N_Port through the network fabric;

wherein network traffic from the first N_Port to the second N_Port is automatically distributed between the first path and the second path by the switch such that frames transmitted in a first direction and related to any single exchange are transmitted over the same path of the first and second path yet frames transmitted in the first direction and related to different but overlapping exchanges need not follow the same path.

- 2. The network of Claim 1, wherein the frames related to the any single exchange are identified by a switch as belonging to the single exchange through fields of a frame header comprising an originator exchange identifier field.
- 3. The network of Claim 2, wherein frames are routed by at least one routing table located within a switch of the at least two switches, the routing table having inputs comprising a hash function of a

- 5 destination identifier of the frame header and at
- 6 least one bit of the originator exchange identifier.
- 1 4. The network of Claim 3, wherein the network
- 2 comprises a switched Fibre Channel/fabric.
- 1 5. The network of Claim 4, wherein the hash function
- 2 has input further comprising a field selected from
- 3 the group consisting of a sour de identifier field of
- 4 the frame header and an incoming port number on which
- the frame was received by the switch.
- 1 6. The network of Claim 4/, wherein the routing table
- 2 produces an index to a sedond table that provides an
- outgoing port identifier for the switch.
- 1 7. The network of Claim 4 wherein a load-balancing
- 2 task of the network updates the at least one routing
- 3 table to alter a distribution of exchanges among
- 4 paths.
- 1 8. The network of Claim 4, wherein the hash function
- 2 further comprises a first hash sub-function of at
- 3 least one bit of the destination identifier and
- having an output, a second hash sub-function of the
- at least one bit of the of iginator exchange
- 6 identifier and having an output, and a concatenation
- 7 operation of the output/of the first hash sub-
- 8 function with the output of the second hash sub-
- 9 function.

9. The network of Claim 8, wherein the second hash sub-function is a bit select operation.

10. The network of Claim 8, wherein f he hash function 1

has inputs further comprising an input selected from

the group consisting of an incoming/port identifier 3

on which the frame was received and at least one bit

of a source identifier field of the frame header. 5

A program product for distr‡buting network traffic between a first N Port ϕ f a network and a 2 second N Port of a network, the network having a plurality of paths for frames from the first N_Port to the second N Port and at least one switch, the program product operable upon/said switch and

comprising computer-readable/code for:

maintaining a routing t/able, the routing table indexed by an output of a hash function of inputs comprising a destination identification field and an originator exchange identifier field of a header of a frame;

causing the routing/table to be accessed upon receipt of a frame, the routing table coupled to determine a selected port for transmission of the frame; and

causing the frame to be transmitted on the selected port.

- The program product of Claim 11, wherein the hash function has inputs/further comprising a an input selected from the group consisting of a source
- identifier field ϕ f the frame header and an identity
- of a switch port upon which the frame was received.
- The program/ product of Claim 11, wherein the 1
- routing table is coupled to determine a selected port 2

by providing an index to a second table that provides
a selected port identifier.

14. A switch for a network capable of distributing frames received on a first port over a plurality of ports, the switch comprising

a plurality of ports including a first port, the first port capable of receiving a frame;

a routing table capable of determining a port of the plurality of ports for forwarding a received frame based upon an address;

a hash function generator capable of generating an address for the routing table based upon information comprising a destination identification field and at least one bit of an originator exchange identifier field of a header of the received frame;

a processor for maintaining the routing table; and

apparatus for receiving a frame and for passing a received frame to the port determined by the routing table.

- 15. The switch of Claim 14 wherein the hash function generator is capable of generating an address for the routing table based upon information further comprising an identifier selected from the group consisting of a source identifier field of the header of the received frame and an port identifier of the switch port on which the frame is received.
- 1 16. The switch of Claim 14, wherein the hash function 2 generator further comprises devices to perform the 3 hash function of a destination identification field

2

- and at least one bit of an originator exchange

 identifier field of the header of the received frame,

 and the routing table comprises a memory capable of

 being addressed by the address generated by the hash

 function.
 - 17. The switch of Claim 16, wherein the memory of the routing table is implemented by at least one RAM, the RAM being writable by the processor and coupled to be addressed through a multiplexor capable of selecting a RAM address from the group of addresses comprising an address generated by the processor and the address generated by the hash function.
